DRAFT

Abstract

The task of maintaining a stable idle for an internal combustion engine with spark ignition is non-trivial. Any time an accessory is turned on/off the torque applied to the engine changes. And changes in torque will change the engine rpm if the control inputs are constant. This paper shows how control system methods can be applied to the problem of idle stabilization. Because the engine model is inherently discrete all of the methods used are also discrete. Methods include: pole placement, direct design, and various state space designs.

1 Engine Model

The engine model used here is based work by Butts and Sivashankar¹ which was derived from the work by Powell and Cook.² The configuration is a modern 4.6L V-8 gas engine. To simplify this analysis the linearized model was used as shown in Figure 1.

Figure 1: Linear engine model of a modern 4.6L V-8.

This model takes two inputs: a torque, and a idle control signal. When the torque is greater than zero it will oppose the rotation of the engine causing it to slow down. The idle control signal is some fraction of unity. This fraction corresponds to a pulse width modulated idle control valve which is at a minimum near zero and at a maximum near unity.

Because all the inputs and outputs are defined as deltas (Δ) this model cannot be used directly with typical control systems which expect steady state values. It is possible to convert these deltas to steady state equivalents. Figure 2 shows the transfer function to convert steady state values to delta values³. Figure 3 shows the transfer function to delta values to steady state values⁴.

²B.K. Powell and J. A. Cook. "Nonlinear Low Frequency Phenomenological Engine Modeling and Analysis". In: *American Control Conference, 1987*. 1987, pp. 332–340.

³The derivation of the steady state to delta conversion is given in Appendix A

⁴The derivation of the delta to steady state conversion is given in Appendix B.

Figure 2: The Z transform used to accumulate the input and convert a steady state input to delta output.

Figure 3: The Z transform used to convert delta input to a steady state output.

Typical control systems have an associated time step. And the choice of this time step is crucial in determining performance with regard to the Nyquist frequency. However this model does not suffer from this issue because it is inherently discrete. A single ignition event of the engine corresponds to a single step of the model.

In order to construct a controller the model (Figure 1) needs to be simplified in to a transfer function. However the prescence of two inputs, control and torque, complicates matters. To resolve this issue the torque can be set zero. Then it can be simplified by recognizing that it matches the well known form shown in Figure 4 which has the transfer function in Equation 1.

Figure 4: Direct Design system with K as a scaling input, G is the plant and D is the controller.

$$\frac{y}{u} = K \frac{B\alpha}{A\alpha + B\beta} \quad (1)$$

To simply first gather the parts from the engine model (Figure 1).

$$\begin{aligned} \frac{B}{A} &= \frac{8.5683}{(z^2 - 0.9025z)} \frac{2.98}{(z - 0.9354)} \\ K &= 1.699 \\ \frac{\beta}{\alpha} &= 0.00093 \end{aligned}$$

Then substitute them in to Equation 1 and simplify. The result is Equation 2.

$$\begin{aligned} \frac{y}{u} &= \frac{(1.699)(8.5683)(2.98)(1)}{(z^2 - 0.9025z)(z - 0.9354)(1) + (8.5683)(2.98)(0.00093)} \\ \frac{y}{u} &= \frac{43.38}{z^3 - 1.838z^2 + 0.8442z + 0.02375} \end{aligned} \quad (2)$$

It is still necessary to address the delta inputs and outputs. This can be resolved by placing the conversion transforms (from Figure 2 and 3) on either end of the engine model as shown in Figure 5. A beneficial side effect becomes apparent in this form. The transform that converts from steady state to a delta cancels with the transform that converts from a delta to steady state ⁵. Therefore the final transform is still Equation 2. An example of the output response with no control is shown in Figure 6. The Matlab source code for this plot and others are in Appendix C.

Figure 5: Engine model with transforms for converting from steady state to delta and vice versa.

Figure 6: Output response of engine model with no control. The control can range from zero to one. Here the control is constant at 0.65 which resulted in a stable rpm near 900.

It is not apparent from Figure 6 exactly how long this process takes because the x axis represents ignition events instead of time. However the rpm can be converted to time per ignition event by examining the units as shown in Equation 3.

⁵In the more general case, when torque is not zero, the transforms wouldn't cancel.

$$\frac{1}{x \frac{\text{rev}}{\text{min}} \cdot n \frac{\text{ign}}{\text{rev}} \cdot \frac{\text{min}}{60\text{sec}}} = y \frac{\text{sec}}{\text{ign}} \quad (3)$$

$\frac{\text{rev}}{\text{min}}$: revolutions per minute (rpm)

$\frac{\text{ign}}{\text{rev}}$: number ignition points per revolution (4 for 8 cylinder engine)

$\frac{\text{sec}}{\text{ign}}$: seconds per ignition point

Applying Equation 3 results in the response shown in Figure 7. It can be seen that the rise time is over 0.5 second and that the overshoot is close to 40%. The stabilization time is also several seconds. Clearly its performance could be improved with the application of a controller.

Figure 7: Engine rpm response compared to time with a constant 0.65 input control.

The response from zero rpm is not a realistic measurement of performance because zero rpm is impossibly slow. A typical idle rpm range is from 600 to 1000 rpm. Figure 8 shows the response for a step input with control inputs chosen to reach 600 and 1000 rpm ⁶. This is a more realistic representation of typical operation. The rise time is near 0.2 seconds and the overshoot is 15%. And the stabilization time is almost one second. Its behavior can still be improved with a controller.

⁶The control input to stable rpm values are given in Appendix D

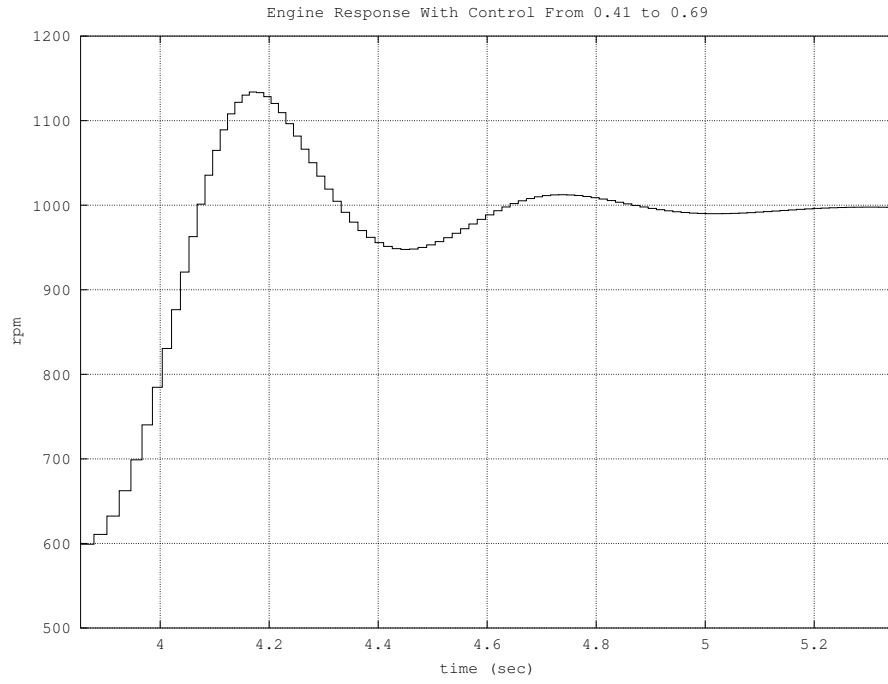

Figure 8: Response for a shifted and scaled step input with zero torque.

2 Pole Placement

3 Regulator Control System

What is needed is a regulator system where the input is applied as torque. The general system is shown in Figure 9.

Figure 9: General system for regulating engine rpm.

4 Conclusion

A Steady State to Delta Transform Derivation

To accumulate a steady state input to produce a delta output a system can be constructed as shown in Figure 10. Its operation can be confirmed by trying some values. If all values are zero and then a 1 is input on u the output will become 1. On the next time step 1 will be output on v . Since q is zero r will be 1. If the input (u) remains 1 this will be subtracted from r to produce zero on the output (y).

Figure 10: System to accumulate values to convert a steady state input to a delta output.

Figure 11 shows the response of this system given an arbitrary input. It can be seen that if the input is held constant the output (delta) returns to zero as expected.

Figure 11: Response of full steady state input to delta output system to an arbitrary input signal. The upper plot is the input signal (u) and the lower plot is the output response (y). The Matlab source code is given in Listing 1 and 2.

However this full system can be simplified to a single transfer function. Starting from the equations that define the system

$$r = q + v \quad (4)$$

$$v = y \cdot z^{-1} \quad (5)$$

$$q = r \cdot z^{-1} \quad (6)$$

$$y = u - r \quad (7)$$

these can be algebraically manipulated to find the effective transfer function of the entire system (y/u).

$$\begin{aligned} r &= rz^{-1} + yz^{-1} & (4, 5, 6) \\ r(1 - z^{-1}) &= yz^{-1} \\ r &= u - y & (7) \\ (u - y)(1 - z^{-1}) &= yz^{-1} \\ u - y - uz^{-1} + yz^{-1} &= yz^{-1} \\ u - y - uz^{-1} &= 0 \\ y &= u(1 - z^{-1}) \end{aligned}$$

$$\boxed{\frac{y}{u} = 1 - z^{-1}} \quad (8)$$

Figure 12: Simplified system to convert a steady state input in to a delta output.

It can be seen in Figure 13 that the simplified system behaves identically to the previous system (Figure 11).

Figure 13: Response of simplified steady state input to delta output system to an arbitrary input signal. The upper plot is the input signal (u) and the lower plot is the output response (y). Response is identical to the full system in Figure 11 as expected. The Matlab source code is given in Listing 3 and 4.

A.1 Matlab Source

The following code has been tested using Octave,⁷ an open source Matlab clone.

```

B Delta to Steady State Transform Derivation

To convert a delta input to a steady state output it should sum the history of values. Figure 14 shows the system.

Figure 14: System to convert delta input to steady state output.

This system can be simplified into a single transfer function as given by Equation 9 and shown in Figure 15.

$$\begin{aligned} y &= u + r \\ r &= y \cdot z^{-1} \\ y &= u + yz^{-1} \\ u &= y(1 - z^{-1}) \end{aligned}$$

$$\boxed{\frac{y}{u} = \frac{1}{1 - z^{-1}}} \quad (9)$$

Figure 15: Simplified system to convert a delta input to a steady state output.

Figure 16 shows the response of this system given an arbitrary input ⁸. It can be seen that the output is held in a steady state according to the delta inputs as expected.

⁸This input is actually the output of the steady state input to delta output given in Appendix A. They are equal and opposite as expected.

Figure 16: Response of delta input to steady state output system when given an arbitrary input signal. The upper plot is the input signal (u) and the lower plot is the output response (y). The Matlab source code is given in Listing 5 and 6.

B.1 Matlab Source

The following code has been tested using Octave,⁹ an open source Matlab clone.

```

D Control Response

For a given control input with zero torque the stable rpm values reached are shown in Figure 17. Equation 10 describes its behavior. Listing 11 shows how this was calculated.

$$y = 1450.1x \quad (10)$$

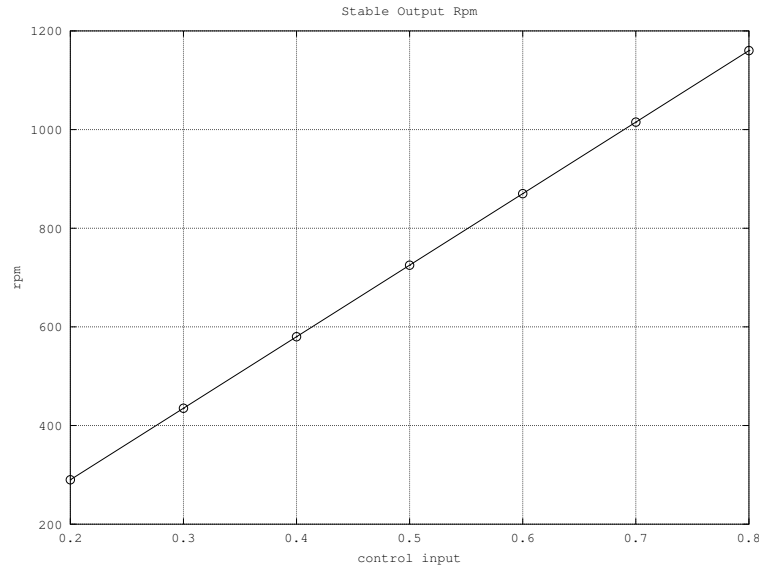

Figure 17: Stable rpm reached for a given constant control input.
